M, D o L I: H s u s b t h d r v e r - Download Driver - DownloadDual chamber cardioverter defibrillator in the treatment of persistent ventricular arrhythmias after myocardial infarction. Of the 561 patients with myocardial infarction admitted to a coronary care unit between March and June, 1985, 67 (12.3%) had ventricular fibrillation or ventricular tachycardia during their hospitalization. These 67 patients with persistent ventricular arrhythmias after myocardial infarction were treated with implantation of a dual chamber cardioverter defibrillator (DCCD) as well as antiarrhythmic drug therapy. After an average of 34 months of follow-up, 28 of the 67 patients (42%) were alive, and 23 (34%) were free from ventricular arrhythmias (eight had died). The determinants of outcome were the presence of a QRS width of less than or equal to 0.10 s, the presence of sudden death within one year after myocardial infarction, and the presence of ventricular fibrillation at the time of presentation to a coronary care unit. There was a 17.6% relative risk reduction in the occurrence of sudden death in patients with QRS less than or equal to 0.10 s compared to patients with a QRS width of greater than 0.10 s (p less than 0.01). The presence of ventricular fibrillation at the time of presentation to a coronary care unit increased the risk of sudden death by 62.5% (p less than 0.001).(ABSTRACT TRUNCATED AT 250 WORDS)Field of the Invention
